South America Workshop

WALC 2006 (Quito, Ecuador – 26-28 July ’06)

Host Configuration
(Windows XP)

Miguel Baptista (miguel.baptista@fccn.pt)
Pedro Lorga (lorga@fccn.pt)
Simon Muyal (muyal@renater.pt)
Laboratory Exercise: *Host Configuration (Windows XP)*

**Objectives**

In this laboratory exercise you will complete the following tasks:

- *Activate the IPv6 protocol stack on WinXP PC’s*
- *Understand basic IPv6 concepts*
- *Manually add/remove IPv6 addresses on Win XP*
- *Disable 6to4 and isatap virtual interfaces*

**Visual Objective**

The following figure shows the topology of the current laboratory. This laboratory is identical with the one on the previous module (*router’s config #1*)

![Scenario topology](image)

*Figure 1: Scenario topology*
Setup

On the previous scenario, for a particular vlan/link, you enabled and configured IPv6 addresses and Router Advertisement Messages. Please, verify that everything is correctly configured, in particular:

- Router advertisement messages interval=30 seconds
- Prefix value in RA messages is **not** suppressed
- vlanXY address=2001:DB8:CAFE:XY:: router_number/64

Scenario

According to the exercises on previous lab, for each vlan, the router is sending periodically the correspondent router advertisement messages. Now that we have IPv6 support on each link, we need to activate IPv6 on our computer’s Operating system, in this case, Windows XP.

Task 1: Enabling IPv6 on Windows XP

Complete the following exercise’s steps

**Step 1:** Enable IPv6 on your Windows XP (SP2)

(Tip: There are two alternative methods to do it)
- Using the WinXP GUI

![IPv6 GUI installation](image)

**Figure 2:** IPv6 GUI installation
- Or from a CLI run `ipv6 install`

**Task 2: Display and identify existing IPv6 addresses**

Complete the following exercise’s steps

**Step 1:** Identify the different interfaces at your PC. Which ones are related to IPv6 transition mechanisms? From a CLI run the following commands:
- `ipconfig /all`
- `netsh interface ipv6 show interface` (look at the end of the document for `netsh` basic information).
- `ipv6 -v if`

**Step 2:** Identify different types of IPv6 addresses (Please notice! You already have IPv6 addresses and you didn’t have to make any configuration on your host machine)
- Link local (Tip: Search for fe80:::)
- auto-configuration IPv6 address (Tip: Search for ff:fe...)
- IPv6 address due to privacy extension
- multicast addresses
- validity of addresses (Tip: Use the command `netsh interface ipv6 show address <interface>`)  

**Task 3: Using some IPv6 related tools**

**Step 1:** Ping local IPv6 addresses
- Ping the IPv6 localhost address (::1)
- Ping your host’s link-local and global addresses

**Step 2:** Without looking into the router, identify the router’s link-local address (for your vlan)
- What’s the appropriate command?
  - Traceroute?
  - Show neighbors?
  - ipconfig?
- Ping router’s addresses (link-local and global addresses). Did you successfully ping router’s link-local address?

**Step 3:** Using `ethereal`, capture router advertisement and router solicitation messages. (Look at the end of the document for `ethereal` basic information).
- Which IPv6 addresses (source - destination) are used in these messages?
In `netsh` command prompt, renew your IPv6 address (Tip: `netsh` `interface ipv6 ?`). Did you capture any router solicitation message? Then, look at the first router advertisement message after the RS message. What’s the source/destination address? Are they equal to the previous RA message? Why?

**Step 4:** Display your current IPv6 routing table (Tip: Use command `netsh` `interface ipv6 show routes level=verbose`).

### Task 4: Add/Remove IPv6 addresses

Complete the following exercise’s steps

**Step 1:** Manually add an IPv6 address

- On your local area connection, add the following address: 2001:DB8:CAFE::10, remember, $XY$=your vlan number

(Tip 1: `netsh ipv6 interface add …`
(Tip 2: `<interface -> interface number or name>`)  

**Step 2:** Manually remove an IPv6 address

- Remove the address created on the previous step (Tip: `netsh ipv6 interface delete …`)

**Step 3:** Disable privacy extensions (RFC3041). (Tip: Use the command `netsh` `interface ipv6 set privacy`

- Check your current addresses
- What could be the problems in terms of security if you enable/disable privacy extension?

**Step 4:** Disable 6to4 and isatap virtual interfaces .

(Tip 1: Use the command `netsh interface ipv6 6to4 set state …`
(Tip 2: Use the command `netsh interface isatap set …`)

Check your current interfaces.

### Summary

After completing these exercises, you should be able to:

- *Enable and configure IPv6 addresses on windows XP*
- *Identify different address types*
- *Manually add/remove IPv6 addresses*
- *Disable 6to4 and isatap virtual interfaces*
Appendix A
Compact “Ethereal” documentation

Ethereal is used by network professionals around the world for troubleshooting, protocol analysis, software and protocol development. Its open source license allows talented experts in the networking community to add enhancements. It runs on all popular computing platforms, including Linux, and Windows. See further information at http://www.ethereal.com/.

In order to capture packets, use the menu (Capture -> Interfaces…). Then choose the interface you want to use and click on the correspondent Prepare button. In the Capture Options window check both “Update list of packets in real time” and “Automatic scrolling in live capture”. Then uncheck both “Enable transport name resolution” and “Enable MAC name resolution” (see figure 3).

Figure 3: Ethereal capture options

If you want to capture only a specific set of packets, use Capture Filter option (in the Capture Options window), as shown in Figure 4. Use the capture filter ipv6 (some Ethereal’s versions uses ip6) to capture only IPv6 packets or icmpv6 to capture only ICMPv6 packets.
After having captured some traffic, you can also filter the results using the *Filter* option, as shown in the Figure 5.

(Tip: Use the filter *ipv6* (some Ethereal’s versions uses *ip6*) to show only IPv6 packets, *icmpv6.code==0* to show ICMP packets of specific code or *http* to show HTTP traffic.)
Appendix B

Using Netsh

Netsh is a command-line scripting utility, for the Windows Operating System, which allows you to display or modify a computer’s network configuration currently running.

Netsh contexts

To run a netsh command, you must start netsh from the CLI prompt and change to the context that contains the command you want to use. The contexts that are available to you depend on which networking components you have installed. For example, if you type dhcp at the Netsh command prompt, you change to the DHCP context, but if you do not have DHCP installed the following message appears:

The following command was not found: dhcp.

Running Netsh commands from the Netsh.exe command prompt

Netsh uses the following standard commands in all contexts that you can run from a Netsh.exe command prompt (that is, netsh>). There might be functional differences between Netsh context commands on Windows 2003 and Windows XP.

1. To view the command syntax, click a command.
2. ..  Moves to the context that is one level up.
3. {/?|?|help|h}  Displays help at the command prompt.
4. Abort  Discards any changes made in offline mode. Abort has no effect in online mode.
5. quit  Exits Netsh.exe

Example

The following sample script changes a context from the root context to the interface ipv6 context and adds an IPv6 address:

C:\> netsh
netsh>
netsh> interface ipv6
netsh interface ipv6>
netsh interface ipv6> add address interface=7 address=2001:ABBA::1
